

NFT Layer Mixer — Simple User Guide

Make NFT art collections in your browser. No install. No coding.

Live app: <https://nft-layer-mixer.vercel.app> **This guide (PDF):** https://nft-layer-mixer.vercel.app/USER_MANUAL.pdf

What is this?

NFT Layer Mixer stacks PNG art layers (background, body, hat, etc.) to create unique NFT images. You control how rare each trait is, preview random rolls, generate a full collection, and download a ZIP with images + metadata.

Everything runs **in your browser**. Your art never uploads to a server.

The three-column dashboard

The screen (3 columns)

Left	Center	Right
Layers & traits	Preview & generate	Settings & export
Rarity weights	Roll the Dice	Collection name
Rules	Bulk generator + batch runs	Download ZIP / Progress

Quick start (5 steps)

1. Open <https://nft-layer-mixer.vercel.app>
2. Demo layers load automatically — click **Roll the Dice** in the center
3. Click **Upload PNGs** on any layer to add your own art
4. Set **Edition Size** on the right (how many NFTs to make)
5. Click **Generate**, then **Export Collection ZIP**

Making thousands of NFTs? Skip step 4–5's one-shot Generate. Use **Batch Collection Run** in the center panel instead (see below).

Preview after rolling the dice

Step 1 — Prepare your art files

Each trait is one PNG (or JPG/WebP) image.

Name files with a weight so rarity is set automatically:

```
Blue Sky#40.png      → name "Blue Sky", weight 40
Gold Crown#5.png     → name "Gold Crown", weight 5
Cyber Hoodie#25.png  → name "Cyber Hoodie", weight 25
```

Higher weight = shows up more often. No #number = weight 1.

Before you upload:

- All layers should be the **same pixel size** (e.g. 1024×1024)
- Use **transparent backgrounds** on every layer except the bottom one
- Layers stack bottom-to-top — background first, accessories last

Step 2 — Set up layers (left column)

Add or rename layers

- Each layer = one category (Background, Body, Hat, etc.)
- Click the layer name to rename
- **Add Layer** for a new category
- Trash icon removes a layer

Upload traits

1. Click **Upload PNGs** on a layer
2. Select your image files
3. Each file becomes one trait

Set rarity (weights)

Every trait has a **Weight**. The app shows the % chance within that layer.

Example — Background layer:

Trait	Weight	Chance
Blue Sky	40	40%
Purple Night	30	30%
Gold Sunset	20	20%
Rare Aurora	10	10%

Quick buttons

- **Equalize** — same weight for every trait in that layer
- **Normalize** — scales weights to add up cleanly

Rarity tier labels

Tags like **Common**, **Rare**, **Legendary** are for your reference. The actual odds come from **weight** numbers. Use the filter pills at the top to focus on one tier.

Step 3 — Rules (optional)

Skip if you don't need special logic.

Dependency rules — "If A, then always B"

Example: **Body / Robot** → always **Headwear / Antenna**

1. Pick Layer A + Trait A (trigger)
2. Pick Layer B + Trait B (forced result)
3. Click **Add Rule**

Exclusion rules — "A and B never together"

Example: **Laser Visor** cannot combine with **Crown**

1. Pick both traits
 2. Click **Add Rule**
-

Step 4 — Preview & generate (center column)

Roll the Dice

One random NFT using your weights and rules. You see the image, a **DNA** code, and every trait picked.

Roll a few times until combos look right.

Generate collection (small / one-off)

For smaller collections that fit comfortably in one browser run (often a few hundred, depending on canvas size):

1. Set **Edition Size** on the right (e.g. 100)
2. Click **Generate [N] NFTs**
3. Watch the progress bar
4. Click **Export Collection ZIP** on the right

Max Unique = how many different combos exist. You can't generate more unique NFTs than that.

If it fails: edition may be too big, or exclusion rules block too many combos.

Batch Collection Run (large collections)

Use this when you want thousands of NFTs (for example ~7,676) without crashing the browser. The app generates **batches** (default **1,000** at a time), keeps every used DNA so later batches never duplicate earlier ones, and continues edition numbers across batches (#1-#1000, then #1001-#2000, and so on).

Important: Browser storage can be cleared. After every batch, keep the downloaded **collection-progress.json** file — that is your recovery source if you refresh, change computers, or lose the session.

Start a run

1. Finish layers, weights, rules, canvas size, and metadata first

(do **not** change layers/rules/canvas mid-run)

1. In the center panel, find **Batch Collection Run**
2. Set **Total target** (e.g. 7676) and **Batch size** (default 1000)
3. Click **Start Run** — batch 1 generates immediately

After each batch

1. Progress shows **Completed / Target**, current **Batch**, and **Next range**
2. A **...-progress-batch1.json** (then batch2, batch3...) file downloads automatically — save it somewhere safe
3. Click **Export Collection ZIP** on the right for that batch's images + metadata

(named like my-cool-apes-batch1-1-1000.zip; the ZIP also includes collection-progress.json)

1. Click **Generate Next [N]** for the following batch
2. Repeat until **Completed** equals your total target

Only the **current batch's images** stay in memory. Earlier image blobs are released after you move on — DNA history is what persists.

Resume later or on another computer

1. Open the same project (same layers, rules, and canvas size)
2. Top bar → **Import Progress** → choose your saved collection-progress.json
3. Click **Generate Next [N]** to continue from the next edition range

You can also click **Progress** anytime to re-download the current progress file.

Reset a run

Click **Reset Run** if you want to start over. This clears DNA history for that run. Keep your old progress file if you might need it again.

If the next batch is blocked

You changed layers, ban/dependency rules, or canvas size after the run started. Restore the original project settings, or reset the run and start fresh.

Step 5 — Export (right column)

Metadata Config

Field	What to put
Collection Name	e.g. My Cool Apes → My Cool Apes #1, #2...
Description	Short blurb about the project
Symbol	Short ticker, e.g. MCA
Royalties (bps)	500 = 5%. Use 0 for none.
External URL	Your website
solana.json	Check if minting on Solana

Generation Settings

Field	What to put
Edition Size	How many NFTs
Canvas Size	512, 1024, or 2048 px output

Export Collection ZIP

After generation (or after each batch), click **Export Collection ZIP**. You get:

```
images/           ← PNGs for this batch (global edition numbering)
metadata/         ← one JSON per NFT
metadata.json     ← master list for this export
rarity-report.json ← trait distribution stats
solana.json       ← optional, for Solana mints
collection-progress.json ← only for batch runs (DNA history + next edition)
```

Batch run ZIP names (easy to sort):

```
my-cool-apes-batch1-1-1000.zip
my-cool-apes-batch2-1001-2000.zip
my-cool-apes-batch3-2001-3000.zip
```

One-off Generate ZIPs still use an edition range + timestamp (no batchN).

Each JSON has name, traits, DNA, edition — ready for most mint tools.

Progress file (batch runs)

Top bar buttons:

Button	What it does
Progress	Download the current progress file (...-progress-batchN.json)
Import Progress	Resume a run from a saved progress file

Progress filenames match the batch number, e.g. my-cool-apes-progress-batch1.json, then ...-batch2.json.

The progress file has **no images** — only DNA history, edition counters, and a fingerprint of your layers/rules/canvas. Keep every batch ZIP **and** the latest progress file.

FAQ

Install anything? No — just open the link in a browser.

Is my art uploaded? No. Stays on your computer until you export the ZIP.

Start over? Refresh the page, or delete layers with the trash icon. For a batch run, use **Reset Run**.

Best format? PNG with transparency.

How many unique NFTs? Multiply trait counts per layer. The app shows **Max Unique** on the right.

Layers misaligned? Make every PNG the same size and aligned in your art tool.

Huge collection (thousands)? Use **Batch Collection Run** (default 1,000 per batch). Don't try one giant Generate — browsers often run out of memory, especially at 2048px.

Lost my batch progress? Import your saved collection-progress.json. If you don't have that file, you'll need to start a new run.

Can I change traits mid-run? No. Keep layers, rules, and canvas size the same until the run finishes (or reset and start over).

Checklist before minting

- ☐ Every layer has traits
- ☐ Weights look right (check % per layer)
- ☐ Rolled dice — combos look good
- ☐ Rules work (if using any)
- ☐ Total editions $\leq$ Max Unique
- ☐ Name + description filled in
- ☐ Generation finished without errors
- ☐ For large collections: all batch ZIPs exported and saved
- ☐ For large collections: latest collection-progress.json saved
- ☐ Spot-checked images + JSON (edition numbers continuous across batches)
